Operations sequencing

APICS CPIM Learning System

The time that a job spends in transit from one operation to another in the plant.	The authoritative route process sheet from which all other format variations and copies are derived.
1) The date when an operation should be completed so that its order due date can be met. It can be calculated based on scheduled quantities and lead times. 2) A job sequencing algorithm (dispatching rule) giving earlier operation due dates higher priority.	A process of gradually reducing the lot size of the number of items in the manufacturing pipeline to expose, prioritize, and eliminate waste.
The date when an operation should be started so that its order due date can be met. Can be calculated based on scheduled quantities and lead times or on the work remaining and the time remaining to complete the job.	A graphical display of the bill of materials and lead-time information provided by the routing for each part. The horizontal axis provides the lead time from raw materials purchase to component manufacture to assembly of the finished product.
A technique for short-term planning of actual jobs to be run in each work center based upon capacity (i.e., existing workforce and machine availability) and priorities. The result is a set of projected completion times for the operations and simulated queue levels for facilities.	The total of setup and run time for a specific task. Syn.: operation duration.

APICS CPIM Learning System

In the theory of constraints, a process in which all expediting in a shop is driven by what is scheduled to A material of value produced as a residual of or be in the buffers (constraint, shipping, and assembly incidental to the production process. The ratio of [this] buffers). By expediting this material into the buffers, the system helps avoid idleness at the constraint and to primary product is usually predictable. [These] may be recycled, sold as-is, or used for other purposes. missed customer due dates. In addition, the reasons See: co-product. items are missing from the buffer are identified, and the frequency of occurrence is used to prioritize improvement activities. A resource that is not a constraint but will become a A product that is usually manufactured together or constraint unless scheduled carefully. Any resource sequentially because of product or process similarities. that, if its capacity is not carefully managed, is likely to See: by-product. compromise the throughput of the organization. The practice of managing resources and organizations Any element or factor that prevents a system from in accordance with the theory of constraints (TOC) achieving a higher level of performance with respect to principles. See: theory of constraints. its goal. In the theory of constraints, strategic locations in the logical product structure for a product or family that

The implementation of solutions resulting in the reduction or elimination of an identified problem.

In the theory of constraints, strategic locations in the logical product structure for a product or family that simplify the planning, scheduling, and control functions. [These] include gating operations, convergent points, divergent points, constraints, and shipping points. Detailed scheduling instructions are planned, implemented, and monitored at these locations. Other work centers are instructed to "work if they have work; otherwise, be prepared for work." In this manner, materials flow rapidly through the facility without detailed work center scheduling and control.

Term Line balancing		
APICS CPIM Learning System	© 2024	

A defined location next to the place of use on a production floor. Materials are brought to [it] as needed and taken from it for immediate use. [These] are used with a pull system of material control.

In just-in-time philosophy, an approach to level production throughout the supply chain to match the planned rate of end product sales.

A form of manufacturing in which the jobs pass through the functional departments in lots, and each lot may have a different routing. See: job shop.

A technique for capacity control where planned and actual inputs and planned and actual outputs of a work center are monitored. Planned inputs and outputs for each work center are developed by capacity requirements planning and approved by manufacturing management. Actual input is compared to planned input to identify when work center output might vary from the plan because work is not available at the work center. Actual output is also compared to planned output to identify problems within the work center. Syn.: input/output analysis. See: capacity control.

The average of worker efficiency for all direct workers in a department or facility. Syn.: worker efficiency.

A method of just-in-time production that uses standard containers or lot sizes with a single card attached to each. It is a pull system in which work centers signal with a card that they wish to withdraw parts from feeding operations or suppliers. [This] Japanese word, loosely translated, means card, billboard, or sign, but other signaling devices such as colored golf balls have also been used. The term is often used synonymously for the specific scheduling system developed and used by the Toyota Corporation in Japan. See: move card, production card, synchronized production.

1) The balancing of the assignment of the tasks to workstations in a manner that minimizes the number of workstations and minimizes the total amount of idle time at all stations for a given output level. In balancing these tasks, the specified time requirement per unit of product for each task and its sequential relationship with the other tasks must be considered. See: uniform plant loading. 2) A technique for determining the product mix that can be run down an assembly line to provide a fairly consistent flow of work through that assembly line at the planned line rate.

A philosophy of production that emphasizes the minimization of the amount of all the resources (including time) used in the various activities of the enterprise. It involves identifying and eliminating non-value-adding activities in design, production, supply chain management, and dealing with customers. [It also employs] teams of multiskilled workers at all levels of the organization and use highly flexible, increasingly automated machines to produce volumes of products in potentially enormous variety. [It] contains a set of principles and practices to reduce cost through the relentless removal of waste and through the simplification of all manufacturing and support processes. Syn.: lean, lean manufacturing.

APICS CPIM Learning System

A variant of scheduling that considers slack time to increase or decrease the calculated lead time of an order. Interoperation and administrative lead time components are expanded or compressed by a uniform "stretching factor" until no difference exists between the schedule of operations obtained by forward and backward scheduling. See: lead time scheduling.

In lean, the resource that is scheduled based on the customer demand rate for that specific value stream; this resource performs an operation or process that governs the flow of materials along the value stream. Its purpose is to maintain a smooth flow through the manufacturing plant. A larger buffer is provided for [this than for] other resources so that it can maintain continuous operation. See: constraint.

A representation of the flow of materials through a process industry manufacturing system that shows equipment and inventories. Equipment that performs a basic manufacturing step, such as mixing or packaging, is called a process unit. Process units are combined into stages, and stages are combined [to form these]. Inventories decouple the scheduling of sequential stages within [this].

Production that adds value by mixing, separating, forming, and/or performing chemical reactions. It may be done in either batch or continuous mode. See: project manufacturing.

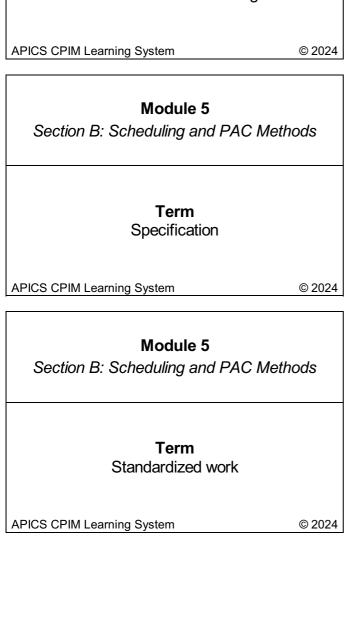

In a just-in-time context, a card or other signal for indicating that items should be made for use or that some items removed from pipeline stock should be replaced. See: kanban.

A technique that schedules equipment (processor) before materials. Facilitates scheduling equipment in economic run lengths and the use of low-cost production sequences. A scheduling method used in some process industries. See: material-dominated scheduling.

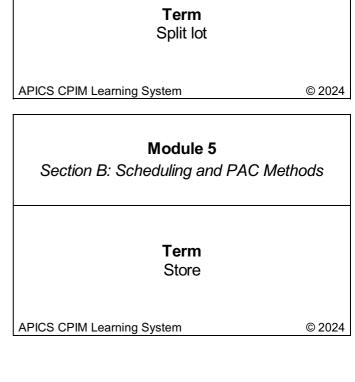

A vehicle to provide feedback to the production schedule and allow for corrective action and maintenance of valid on-hand and on-order balances. Normally includes manufacturing order authorization, release, acceptance, operation start, delay reporting, move reporting, scrap and rework reporting, order close-out, and payroll interface. Syn.: manufacturing order reporting, shop order reporting.

A production planning method that maintains a stable production rate while varying inventory levels to meet demand.

The scheduling of activities so that predetermined resource availability pools are not exceeded. Activities are started as soon as resources are available (with respect to logical constraints), as required by the activity. When not enough of a resource exists to accommodate all activities scheduled on a given day, a priority decision is made. Project finish may be delayed, if necessary, to alter schedules constrained by resource usage.

Any signal that indicates when to produce or transport items in a pull replenishment system. For example, in just-in-time production control systems, a kanban card is used as [this] to replenish parts to the using operation. See: pull system.

One of the three devices required for proper management of operations. (The other two are drum and buffer.) The rope is the information flow from the drum to the front of the line (material release), which chokes the release of materials to match the flow through the constraint.

A scheduling procedure used in some process industries for building process train schedules. Starts with the last stage and proceeds backward (countercurrent to the process flow) through the process structure.

A manufacturing order quantity that has been divided into two or more smaller quantities, usually after the order has been released. The quantities of [this] may be worked on in parallel, or a portion of the original quantity may be sent ahead to a subsequent operation to be worked on while work on the remainder of the quantity is being completed at the current operation. The [purpose...] is to reduce the lead time of the order.

A clear, complete, and accurate statement of the technical requirements of a material, an item, or a service, and of the procedure to determine if the requirements are met.

A storage point located upstream of a work station, intended to make it easier to see customer requirements.

A work process that is always carried out exactly the same way, preferably using the current best known way under which the output can be achieved.

Unplanned repair

APICS CPIM Learning System

A holistic management philosophy developed by Dr. Eliyahu M. Goldratt, based on the principle that complex systems exhibit inherent simplicity. Even a very complex system comprising thousands of people and pieces of equipment can have, at any given time, only a very, very small number of variables—perhaps only one, known as a constraint—that actually limit the ability to generate more of the system's goal.

Sets the pace of production to match the rate of customer demand and becomes the heartbeat of any lean production system. Computed as the available production time divided by the rate of customer demand. For example, assume demand is 10,000 units per month, or 500 units per day, and planned available capacity is 420 minutes per day. [This] = 420 minutes per day ÷ 500 units per day = 0.84 minutes per unit. [This... means] that a unit should be planned to exit the production system on average every 0.84 minutes. Syn.: tact time.

Allowable departure from a nominal value established by design engineers that is deemed acceptable for the functioning of the good or service over its life cycle.

Protection against uncertainty that takes the form of time.

The quantity of an item moved between sequential work centers during production. See: batch, overlap quantity.

1) The upper and lower extreme values permitted by the tolerance. 2) In work measurement, the limits between which a specified operation time value or other work unit will be expected to vary. See: lower specification limit, upper specification limit. Syn.: specification limits.

Repair and replacement requirements that are unknown until remanufacturing teardown and inspection.

A kanban system where a move card and production card are employed. The move card authorizes the movement of a specific number of parts from a source to a point of use. The move card is attached to the standard container of parts during movement of the parts to the point of use. The production card authorizes the production of a given number of parts for use or replenishment. Syn.: dual-card kanban system. See: one-card kanban system.

APICS CPIM Learning System

In the theory of constraints, a procedure for determining the general flow of parts and products from raw materials to finished products (logical product structure). [The "V"] logical structure starts with one or a few raw materials, and the product expands into a number of different products as it flows through divergent points in its routings. The shape of an ["A"] logical structure is dominated by converging points. Many raw materials In statistical process control, the line that defines the are fabricated and assembled into a few finished products. [The "T"] maximum acceptable level of random output. See: logical structure consists of numerous similar finished products assembled from common assemblies, subassemblies, and parts. An ["I"] tolerance limits. logical structure is the simplest of production flows, where resources are shared between different products and the flow is in a straight line sequence (e.g., an assembly line). Once the general parts flow is determined, the system control points (gating operations, convergent points, divergent points, constraints, and shipping points) can be identified and managed. 1) Arrangement in which companies exchange their wastes for the benefit of both parties. 2) An exchange service of valuable information between generators and The control of authorized levels of activities and potential users of industrial and commercial wastes, inventories in a way that is instantly and visibly whereby a beneficial use rather than disposal is the obvious. A type of activity and inventory control used in end result. This service identifies both the producers a workplace organization where everything has an and potential markets for by-products, surpluses, assigned place and is in its place. unspent materials, and other forms of solid waste that is no longer needed. A routing that is usually less preferred than the primary routing but results in an identical item. [This] may be maintained in the computer or off-line via manual Putting a resource to work. methods, but the computer software must be able to accept alternate routings for specific jobs. The number of hours a work center can be used, based on management decisions regarding shift The percentage of time that a worker or machine is structure, extra shifts, regular overtime, observance of capable of working. The formula is where S is the weekends and public holidays, shutdowns, and the scheduled time and B is the downtime. like. See: capacity available, utilization.

Demonstrated capacity

APICS CPIM Learning System

1) The capability of a system to perform its expected function. 2) The capability of a worker, machine, work center, plant, or organization to produce output per time period. Capacity required represents the system capability needed to make a given product mix (assuming technology, product specification, etc.). As a planning function, both capacity available and capacity required can be measured in the short term (capacity requirements plan), intermediate term (rough-cut capacity plan), and long term (resource requirements plan). Capacity control is the execution through the I/O control report of the short-term plan. Capacity can be classified as budgeted, dedicated, demonstrated, productive, protective, rated, safety, standing, or theoretical. See: capacity available, capacity required. 3) Required mental ability to enter into a contract.

The volume/mix of throughput on which financial budgets were set and overhead/burden absorption rates established.

The process of measuring production output and comparing it with the capacity plan, determining if the variance exceeds pre-established limits, and taking corrective action to get back on plan if the limits are exceeded. See: input/output control.

The capability of a system or resource to produce a quantity of output in a particular time period. Syn.: available capacity. See: capacity, available time.

The process of determining the amount of capacity required to produce in the future. This process may be performed at an aggregate or product-line level [...], at the master-scheduling level [...], and at the material requirements planning level [...]. See: capacity requirements planning, resource planning, rough-cut capacity planning.

The function of establishing, measuring, monitoring, and adjusting limits or levels of capacity in order to execute all manufacturing schedules (i.e., the production plan, master production schedule, material requirements plan, and dispatch list). [It] is executed at four levels: resource requirements planning, rough-cut capacity planning, capacity requirements planning, and input/output control.

Proven capacity calculated from actual performance data, usually expressed as the average number of items produced multiplied by the standard hours per item. See: maximum demonstrated capacity.

The capacity of a system or resource needed to produce a desired output in a particular time period. Syn.: required capacity. See: capacity.

The available capacity that exists on nonconstraint resources beyond the capacity required to support the constraint. [It] has two components: protective capacity and excess capacity.

A measurement (usually expressed as a percentage) of the actual output relative to the standard output expected. [This] measures how well something is performing relative to existing standards; in contrast, productivity measures output relative to a specific input (e.g., tons/labor hour). [It] is the ratio of (1) actual units produced to the standard rate of production expected in a time period, or (2) standard hours produced to actual hours worked (taking longer means less [of this]), or (3) actual dollar volume of output to a standard dollar volume in a time period. For example: (1) There is a standard of 100 pieces per hour and 780 units are produced in one eight-hour shift; [this] is 780 ÷ 800 converted to a percentage, or 97.5 percent. (2) The work is measured in hours and took 8.21 hours to produce 8 standard hours; [this] is 8 ÷ 8.21 converted to a percentage, or 97.5 percent. (3) The work is measured in dollars and produces \$780 with a standard of \$800; [this] is \$780 ÷ \$800 converted to a percentage, or 97.5 percent.

A partial productivity measure in which the rate of output of a worker or group of workers per unit of time is compared to an established standard or rate of output. [This] can be expressed as output per unit of time or output per labor hour. See: machine productivity, productivity.

The time when operators or resources (e.g., machines) are not producing product because of setup, maintenance, lack of material, lack of tooling, or lack of scheduling.

A display of future capacity requirements based on released and/or planned orders over a given span of time. Syn.: load projection. See: capacity requirements plan.

The amount of planned work scheduled for and actual work released to a facility, work center, or operation for a specific span of time. Usually expressed in terms of standard hours of work or, when items consume similar resources at the same rate, units of production. Syn.: workload.

The accumulation by workstation, machine, or machine group of the hours generated from the scheduling of operations for released orders by time period. [This] differs from capacity requirements planning in that it does not use the planned orders from MRP but operates solely from released orders. It may be of limited value because of its limited visibility of resources.

A production area consisting of one or more machines (and, if appropriate for capacity planning, the necessary support personnel) that can be considered as one unit for capacity requirements planning and detailed scheduling.

Standard time

APICS CPIM Learning System

The standard hours of work required by planned production orders.

A calendar used in inventory and production planning functions that consecutively numbers only the working days so that the component and work order scheduling may be done based on the actual number of workdays available. Syn.: M-day calendar, planning calendar, production calendar, shop calendar. See: resource calendar.

1) An overall measure of the ability to produce a good or a service. It is the actual output of production compared to the actual input of [resources, and] is a relative measure across time or against common entities (labor, capital, etc.). In the production literature, attempts have been made to define [its total] where the effects of labor and capital are combined and divided into the output. One example is a ratio that is calculated by adding the dollar value of labor, capital equipment, energy, and material, and so forth and dividing it into the dollar value of output in a given time period. This is one measure of [the total factor type of this.] See: efficiency, labor productivity, machine productivity, utilization. 2) In economics, the ratio of output in terms of dollars of sales to an input such as direct labor in terms of the total wages. Known as single factor productivity or partial factor productivity.

In the theory of constraints, the maximum of the output capabilities of a resource (or series of resources) or the market demand for that output for a given time period. See: excess capacity, idle capacity, protective capacity.

1) Information detailing the method of manufacture of a particular item. It includes the operations to be performed, their sequence, the various work centers involved, and the standards for setup and run. In some companies, [this] also includes information on tooling, operator skill levels, inspection operations and testing requirements, and so on. Syn.: bill of operations, instruction sheet, manufacturing data sheet, operation chart, operation list, operation sheet, route sheet, routing sheet. See: bill of labor, bill of resources. 2) In information systems, the process of defining the path a message will take from one computer to another computer.

The expected output capability of a resource or system. Capacity is traditionally calculated from such data as planned hours, efficiency, and utilization. [This] is equal to hours available × efficiency × utilization. Syn.: calculated capacity, effective capacity, nominal capacity, standing capacity.

The length of time that should be required to (1) set up a given machine or operation and (2) run one batch or one or more parts, assemblies, or end products through that operation. Used in determining machine requirements and labor requirements. Assumes an average worker who follows prescribed methods, and allows time for personal rest to overcome fatigue and unavoidable delays. Also frequently used as a basis for incentive pay systems and as a basis of allocating overhead in cost accounting systems. Syn.: standard hours. See: standard.

The standard hours of work required by scheduled receipts (i.e., open production orders).

APICS CPIM Learning System

A document, group of documents, or schedule conveying authority for the manufacture of specified parts or products in specified quantities. Syn.: job order, manufacturing authorization, production order, production release, run order, shop order, work order. See: assembly parts list, batch card, blend order, fabrication order, mix ticket, work order.

The practice of an employee periodically changing job responsibilities to provide a broader perspective and a view of the organization as a total system, in order to enhance motivation and provide cross-training.

1) An order to the machine shop for tool manufacture or equipment maintenance; not to be confused with a manufacturing order. Syn.: work ticket. 2) An authorization to start work on an activity (e.g., maintenance) or product.
